

Q1. Given an array of integers `nums` and an integer `target`, return indices of the two numbers such that they add up to `target`. You may assume that each input would have exactly one solution, and you may not use the same element twice. You can return the answer in any order.

Example: Input: `nums = [2,7,11,15]`, `target = 9` Output: `[0,1]`

Explanation: Because `nums[0] + nums[1] == 9`, we return `[0, 1]` """

```
def twoSum(nums, target):
```

```
    d = {}
```

```
    for i, num in enumerate(nums):
        j = target - num
```

```
        if j in d:
            return [d[j], i]
```

```
    d[num] = i
    return []
```

```
nums = [2, 7, 11, 15] target = 9 result = twoSum(nums, target) print(result)
```

```
""" Output:
```

```
[Running] python -u "/config/workspace/practices/ass1Q1.py" [0, 1] [Done] exited
with code=0 in 0.025 seconds
```

""" """   **Q2.** Given an integer array `nums` and an integer `val`, remove all occurrences of `val` in `nums` in-place. The order of the elements may be changed. Then return the number of elements in `nums` which are not equal to `val`. Consider the number of elements in `nums` which are not equal to `val` be `k`, to get accepted, you need to do the following things:

- Change the array `nums` such that the first `k` elements of `nums` contain the elements which are not equal to `val`. The remaining elements of `nums` are not important as well as the size of `nums`.
- Return `k`.

Example : Input: `nums = [3,2,2,3]`, `val = 3` Output: `2`, `nums = [2,2,*,*]`

Explanation: Your function should return `k = 2`, with the first two elements of `nums` being `2`. It does not matter what you leave beyond the returned `k` (hence they are underscores)

```
"""
```

```
def remove(nums, val): i = 0
```

```

for j in range(len(nums)):
    if nums[j] != val:
        nums[i] = nums[j]
        i += 1

return i
nums = [3, 2, 2, 3] val = 3 k = remove(nums, val) print(k)
print(nums[:k])

```

""" Output:

[Running] python -u "/config/workspace/practices/ass1Q2.py" 2 [2, 2] [Done] exited with code=0 in 0.025 seconds

"""

"""  **Q3.** Given a sorted array of distinct integers and a target value, return the index if the target is found. If not, return the index where it would be if it were inserted in order.

You must write an algorithm with $O(\log n)$ runtime complexity.

Example 1: Input: nums = [1,3,5,6], target = 5

Output: 2

"""

```

def search(nums, target): left = 0 right = len(nums) - 1

while left <= right:
    mid = (left + right)

    if nums[mid] == target:
        return mid
    elif nums[mid] < target:
        left = mid + 1
    else:
        right = mid - 1

return left
nums = [1, 3, 5, 6] target = 5 index = search(nums, target) print(index)

```

""" Output: write an algorithm with $O(\log n)$ runtime complexity --> $O(\log n)$

[Running] python -u "/config/workspace/practices/tempCodeRunnerFile.py" 2

[Done] exited with code=0 in 0.026 seconds

```
"""
```

"""   **Q4.** You are given a large integer represented as an integer array `digits`, where each `digits[i]` is the *i*th digit of the integer. The digits are ordered from most significant to least significant in left-to-right order. The large integer does not contain any leading 0's.

Increment the large integer by one and return the resulting array of digits.

Example 1: Input: `digits = [1,2,3]` Output: `[1,2,4]`

Explanation: The array represents the integer 123.

Incrementing by one gives $123 + 1 = 124$. Thus, the result should be `[1,2,4]`.

```
"""
```

```
def Add(digit): n = len(digit)
for i in range(n - 1, -1, -1):
    digit[i] += 1
    if digit[i] < 10:
        return digit
    digit[i] = 0
digit.insert(0, 1)
return digit
digit = [1, 2, 3] result = Add(digit) print(result)
